Networking Setup

## Nameserver Selection

A nameserver is a program that maintains a list of your domain names and their corresponding IP addresses, allowing visitors to find the domains hosted on your server. It is a vital component of the networking setups of most servers. However, servers using a remote nameserver do not need to configure their own.

Here you can select the nameserver you wish to use, if any.

	Nameserver	Advantages	Disadvantages	Notes
<input checked="" type="radio"/>	<b>BIND</b>	<ul style="list-style-type: none"><li>Configuration file can be manually edited.</li><li>Extremely configurable.</li><li>Provides a caching nameserver.</li><li>Very tolerant of syntax errors in zone files.</li></ul>	<ul style="list-style-type: none"><li>Large memory footprint.</li></ul>	
<input type="radio"/>	<b>PowerDNS</b>	<ul style="list-style-type: none"><li>Very high performance.</li><li>Instant start-up.</li><li>Low memory requirements.</li></ul>	<ul style="list-style-type: none"><li>Does not provide a recursive (caching) nameserver. (requires external nameservers in resolv.conf (/cpsess5613815762/scripts2/setupresolvconf))</li><li>CPU intensive with a high volume of DNS zones that use DNSSEC</li></ul>	<ul style="list-style-type: none"><li>This is the default choice.</li><li>Built-in support for DNSSEC.</li></ul>
<input type="radio"/>	<b>MyDNS</b> Deprecated	<b>Warning:</b> MyDNS is deprecated and we will remove it in a future release.		
<input type="radio"/>	<b>NSD</b> Deprecated	<b>Warning:</b> NSD is deprecated and we will remove it in a future release.		
<input type="radio"/>	<b>Disabled</b>			<ul style="list-style-type: none"><li>This option will disable the nameserver. If you are serving dns as part of a cluster you may not need to run one locally.</li></ul>
